

- When conducting the work of Lab 11, we conducted the test that uses the Central Limit Theorem even though the sample size was “small” (i.e.,  $n < 30$ ). It turns out, that how “far off” the  $t$ -test is can be computed using a first-order Edgeworth approximation for the error. Below, we will do this for the the further observations.

(a) Boos and Hughes-Oliver (2000) note that

$$P(T \leq t) \approx F_Z(t) + \underbrace{\frac{\text{skew}}{\sqrt{n}} \frac{(2t^2 + 1)}{6}}_{\text{error}} f_Z(t),$$

where  $f_Z(\cdot)$  and  $F_Z(\cdot)$  are the Gaussian PDF and CDF and skew is the skewness of the data. What is the potential error in the computation of the  $p$ -value when testing  $H_0 : \mu_X = 0; H_a : \mu_X < 0$  using the zebra finch further data?

```
library(tidyverse)
library(e1071)
dat1 = read_csv("zebrafinches.csv")

## Rows: 25 Columns: 3
## -- Column specification -----
## Delimiter: ",",
## dbl (3): closer, further, diff
##
## i Use 'spec()' to retrieve the full column specification for this data.
## i Specify the column types or set 'show_col_types = FALSE' to quiet this message.

dat = dat1$`further`
t.val = as.numeric(t.test(dat, alternative = "less", mu = 0)$statistic)
cdf.val = pnorm(t.val)
pdf.val = dnorm(t.val)
skew = skewness(dat)
n = length(dat)
(error = cdf.val + (skew/sqrt(n)*(2*(t.val)^2+1)/6*pdf.val))

## [1] -1.189164e-13
```

- Compute the error for  $t$  statistics from -10 to 10 and plot a line that shows the error across  $t$ . Continue to use the skewness and the sample size for the zebra finch further data.

```
total.error = vector()
seq = seq(-10,10,.01)
for(t in seq){
  curr.cdf.val = pnorm(t)
  curr.pdf.val = dnorm(t)
  skew = skewness(dat)
  n = length(dat)
  curr.error = (skew/sqrt(n)*(2*(t)^2+1)/6*curr.pdf.val)
  total.error = append(total.error, curr.error)
}
total.error = tibble(x = total.error) |>
mutate(seq)
```

- (c) Suppose we wanted to have a tail probability within 10% of the desired  $\alpha = 0.05$ . Recall we did a left-tailed test using the further data. How large of a sample size would we need? That is, we need to solve the error formula equal to 10% of the desired left-tail probability:

$$0.10\alpha \stackrel{set}{=} \underbrace{\frac{\text{skew}}{\sqrt{n}} \frac{(2t^2 + 1)}{6} f_Z(t)}_{\text{error}},$$

which yields

$$n = \left( \frac{\text{skew}}{6(0.10\alpha)} (2t^2 + 1) f_Z(t) \right)^2.$$

```
t.val.c = qnorm(.05)
pdf.val.c = dnorm(t.val.c)
(n.c = (skew/(6*(.1*.05))*(2*t.val.c^2+1)*pdf.val.c)^2)

## [1] 520.8876
```

2. Complete the following steps to revisit the analyses from lab 11 using the bootstrap procedure.

- (a) Now, consider the zebra finch data. We do not know the generating distributions for the closer, further, and difference data, so perform resampling to approximate the sampling distribution of the  $T$  statistic:

$$T = \frac{\bar{x}_r - 0}{s/\sqrt{n}},$$

where  $\bar{x}_r$  is the mean computed on the  $r^{th}$  resample and  $s$  is the sample standard deviation from the original samples. At the end, create an object called `resamples.null.closer`, for example, and store the resamples shifted to ensure they are consistent with the null hypotheses at the average (i.e., here ensure the shifted resamples are 0 on average, corresponding to  $t = 0$ , for each case).

```
#Farther
t.dist.dat = vector()
s = sd(dat)
for(i in 1:10000){
  curr.val = (mean(sample(dat, replace = TRUE)) - 0)/(s/sqrt(n))
  t.dist.dat = append(t.dist.dat, curr.val)
}
ncp = -1*(mean(t.dist.dat))
resamples.null.farther = t.dist.dat + ncp
(mean(resamples.null.farther))

## [1] 4.4591e-16

#Closer
t.close.dat = vector()
s = sd(dat1$closer)
for(i in 1:10000){
  curr.val = (mean(sample(dat1$closer, replace = TRUE)) - 0)/(s/sqrt(n))
  t.close.dat = append(t.close.dat, curr.val)
}
ncp2 = -1*(mean(t.close.dat))
resamples.null.closer = t.close.dat + ncp2
(mean(resamples.null.closer))

## [1] 1.387557e-16

#Difference
t.diff.dat = vector()
s = sd(dat1$diff)
for(i in 1:10000){
  curr.val = (mean(sample(dat1$diff, replace = TRUE)) - 0)/(s/sqrt(n))
  t.diff.dat = append(t.diff.dat, curr.val)
}
ncp3 = -1*(mean(t.diff.dat))
resamples.null.diff = t.diff.dat + ncp3
(mean(resamples.null.diff))

## [1] 2.775558e-18

**Hint:** You can “search” for the lower bound from  $Q_1$  and subtracting by 0.0001, and the upper bound using  $Q_3$  and increasing by 0.0001. You will continue until you find the first value for which the two-sided  $p$ -value is greater than or equal to 0.05.

4. **Optional Challenge:** In this lab, you performed resampling to approximate the sampling distribution

of the  $T$  statistic using

$$T = \frac{\bar{x}_r - 0}{s/\sqrt{n}}.$$

I'm curious whether it is better/worse/similar if we computed the statistics using the sample standard deviation of the resamples ( $s_r$ ), instead of the original sample ( $s$ )

$$T = \frac{\bar{x}_r - 0}{s_r/\sqrt{n}}.$$

- (a) Perform a simulation study to evaluate the Type I error for conducting this hypothesis test both ways.
- (b) Using the same test case(s) as part (a), compute bootstrap confidence intervals and assess their coverage – how often do we ‘capture’ the parameter of interest?
